We are looking for a matrix Γ that fulfills $B = \Gamma B'$

with $B = \begin{pmatrix} -1 & 0 \\ 2 & 1 \end{pmatrix}$ and $B' = \begin{pmatrix} 3 & 1 \\ 4 & 1 \end{pmatrix}$ the matrix representing the problem is:

$$\left(\begin{array}{cccc|c} 3 & 4 & 0 & 0 & -1 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 3 & 4 & 2 \\ 0 & 0 & 1 & 1 & 1 \end{array} \right)$$

which can be formed into

$$\left(\begin{array}{cccc|c} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 & 2 \\ 0 & 0 & 0 & 1 & -1 \end{array} \right)$$

hence

$$\Gamma = \begin{pmatrix} 1 & -1 \\ 2 & -1 \end{pmatrix}$$

5

- (a) let B be a Basis of V , then $\text{Rang}_K \Phi = \dim_K \text{span}(\Phi(B))$. There is exactly $\dim_K V$ elements in $\text{span}(\Phi(B))$ and some of them might as well be linearly dependent. So we can reduce the span to only linear independent vectors B' (which is a basis of the image space). hence we have $\text{Rang}_K \Phi \leq \dim_K V$. From the definition of Φ we know that $\text{Im}(\Phi) \subseteq W$ thus $\text{Rang}_K \Phi \leq \dim_K W$
- (b) in the case of Ψ being surjective we can find a set of C_j such that $B_j = \Psi(C_j)$ hence $\text{Im}(\Phi\Psi) = \text{Im}(\Phi)$.
if Ψ is not surjective, there must be at least one B_k for which we cannot find a C_k hence $B'_k \notin \text{span}(\Phi\Psi C_j)$ and $\text{Rang}(\Phi\Psi) < \text{Rang}(\Phi)$

- (c) in the case of Θ being injective, we know that B'_j are mapped to linearly independent vectors $\Theta(B'_j)$ hence $\dim(\text{Im}(\Theta\Phi)) = \dim(\text{Im}\Phi)$. For Θ linear and not injective, we can find a new basis B^* of $\text{Im}\Phi$ such that at least two of the B_j get mapped to the same $D_{*j} = \Theta(B_{*j})$. We do this by picking two vectors from $\text{Im}\Phi$ that are mapped to the same vector in Z (If there are no such two vectors, then Θ is injective on $\text{Im}\Phi$ which gives us equality as above). If the two vectors are linearly dependent, we make them independent by adding a linearly independent vector of our old basis. By linearity the two vectors still are mapped to the same vector in Z . From these two vectors we can construct a basis by appending linearly independent vectors of our old basis. Hence for this basis it is easy to see that $\dim(\text{span}(\Theta\Phi(B^*))) \leq \dim(\text{span}(\Phi(B^*)))$.

6

- (a) if we have a permutation $\pi = (j_1, j_2, \dots, j_n)$ and swap exactly two numbers j_k and j_l with $k < l$ we get a new permutation $\pi_1 = (j_1, j_2, \dots, j_{k-1}, j_l, j_{k+1}, \dots, j_{l-1}, j_k, j_{l+1}, \dots, j_n)$ in this permutation we now have some m of the $l - k$ elements that are in between, which have larger indices and moved to the left of the k 'th. On the other hand we have $l - k - m$ elements with smaller indices for which k moved to the right. So we have a difference of $2m - l + k$ of terms in the exponent. Similarly we find that for the l 'th element the difference is some $2p - l - k$. which gives in total $2m + 2p - 2l + 2k$ and since for the k 'th element not only m elements from inbetween, but also the l 'th element are now left, the exponent changes by an odd number which leads to the inversion of the sign
- (b) let's take the ordered permutation of n numbers and permute only the first 2: we get exactly 2 permutations, one is even and one is odd. Now let's permute the third element with the first two positions, where the first two positions are considered identical, since we already have all permutations of the first two elements. There are 3 permutations for the third element, some change sign, some don't, but as we started with the same amount of even and odd permutations, for every even permutation that is now odd, there is an odd permutation that is now even. Thus when we combine, we get 2×3 permutations, of which half are even and half are odd. For the n 'th element we therefore get $2 \times 3 \times \dots \times n = n!$ permutations, of which half are even and half are odd.
- (c) we look for the first element. for each element in f_1 , i.e. for each element that is left of 1, but bigger than one, we do a pair inversion starting with the rightmost element. Now 1 is in its natural position. after doing this $n - 1$ times we notice that the $n - 1$ first positions are in natural order and that the n 'th element can only be in its natural position, too. Hence we did $\sum_{k=1}^{n-1} f_k$ pairwise inversions to get to the natural permutation.

7

$$\begin{aligned}
\det \begin{pmatrix} 1 & 3 & 0 & 4 \\ 0 & 0 & 1 & -1 \\ 1 & 2 & \pi & 49 \\ 0 & 1 & \frac{1}{2} & 3 \end{pmatrix} &= -(1 * 1 * 2 * 3) + (1 * 1 * 49 * 1) + (1 * (-1) * 2 * \frac{1}{2}) \\
&\quad - (1 * (-1) * \pi * 1) + (3 * 1 * 1 * 3) + (3 * (-1) * 1 * \frac{1}{2}) - (4 * 1 * 1 * 1) \\
&= -6 + 49 - 1 + \pi + 9 + \frac{3}{2} - 4 \\
&= 48 + \frac{1}{2} + \pi
\end{aligned}$$

$$\begin{aligned}
\det \begin{pmatrix} i & 8 & 1+i \\ -2+5i & 4-2i & -5 \\ 1+3i & -2i & 5 \end{pmatrix} &= (i(4-2i)5) - (i(-2i)(-5)) + (8(-5)(1+3i)) \\
&\quad - (8(-2+5i)5) + ((1+i)(-2+5i(-2i))) - ((1+i)(4-2i)(1+3i)) \\
&= 20i+10+10-40-120i+80-200i+((1+i)(4i+10))-((1+i)(4+12i-2i+6)) \\
&= -300i+60+4i+10-4+10i-10-20i+10 \\
&= -306i+66
\end{aligned}$$

$$\det \begin{pmatrix} 23 & 7 & 8 & 14 & 1 \\ 117 & 0 & 3 & 1 & 4 \\ 24 & 3 & 1 & 1 & 1 \\ 8 & 12 & 0 & \pi & 3 \\ 6 & -9 & 1 & 1-\pi & -2 \end{pmatrix}$$

we can add the last and the secondlast row to see it is identical to the third row:

$$= \begin{pmatrix} 23 & 7 & 8 & 14 & 1 \\ 117 & 0 & 3 & 1 & 4 \\ 24 & 3 & 1 & 1 & 1 \\ 24 & 3 & 1 & 1 & 1 \\ 6 & -9 & 1 & 1-\pi & -2 \end{pmatrix}$$

Hence the rows of the matrix are linearly dependent and the determinant is $\det A = 0$
